

Executive Summary

Milestone 2 of the TikTok Claims Classification Project

ISSUE / PROBLEM

TikTok data team seeks to build a machine learning model to assist in the classification of claims submissions by user. The data team needs to organize the raw dataset and prepare it for the future exploratory data analysis.

RESPONSE

The data team performed preliminary investigation of the claims dataset with the aim learning important relationship between variables.

The data team looked at the counts of claims and opinions in order to understand the count of each video content.

IMPACT

The data team identified two important variables to consider, video duration (in seconds), video view count for future prediction models.

Understanding the data:

From the data the claim status was particularly useful, given the counts of the claim status below are quite balanced.

```
data['claim_status'].value_counts()
```

```
claim      9608
opinion     9476
Name: claim status, dtype: int64
```

Engagement trends:

The data team considered viewer engagement with each video in the claim and opinion category.

In order to understand the viewer engagement the data team considered the view count. The mean and median view count show the impact of each category of video (claim or opinion).

Claims:

mean: 501029.4527477102
median: 501555.0

Opinions:

mean: 4956.43224989447
median: 4953.0

KEY INSIGHTS

The count of videos of opinions and claims are nearly equal. With this understanding we can proceed with our future analysis knowing that there is fairly balanced amount of claims and opinions included in this dataset.

With the key variables identified and the initial investigation of the claims classification dataset, the process of exploratory data analysis can begin.

Total number of claims vs opinions
